ABSTRACT

SOME ABSTRACT

Contents

Nomenclature

Constants of nature

G - Gravitational constant. $G = 6.6743\times10^{-11}$ m^3 kg^{-1} s^{-2}.
k_B - Boltzmann constant. $k_B = 1.3806 \times 10^{-23}$ m^2 kg s^{-2} K^{-1}.
$\hbar$ - Reduced Planck constant. $\hbar = 1.0546 \times 10^{-34}$ J s^{-1}.
c - Speed of light in vacuum. $c = 2.9979 \times 10^8$ m s^{-1}.

Cosmological parameters

H - Hubble parameter.
H_0 - Hubble constant fill in stuff.
$e^x\mathcal{H}$ - Scaled Hubble parameter.
$T_{\rm CMB0}$ - Temperature of CMB today. $T_{\rm CMB0} = 2.7255$ K.
η - Conformal time.
χ - Co-moving distance.

Density parameters

Density parameter $\Omega_X = \rho_X/\rho_c$ where ρ_X is the density and $\rho_c = 8\pi G/3H^2$ the critical density. X can take the following values:

b - Baryons.
CDM - Cold dark matter.
γ - Electromagnetic radiation.
ν - Neutrinos.
k - Spatial curvature.
Λ - Cosmological constant.

A 0 in the subscript indicates the present day value.

1. Introduction

Some citation Dodelson & Schmidt (2020) and Weinberg (2008)

Also write about the following:

- Cosmological principle

Fig. 1. Penguin making sure that you do all the work necessary!

- Einstein field equation
- Homogeneity and isotropy
- FLRW metric

In order to explain the connection between spacetime itself and the energy distribution within it we must solve the Einstein equation:

$$G_{\mu\nu} = 8\pi G T_{\mu\nu}, \tag{1}$$

where $G_{\mu\nu}$ is the Einstein tensor describing the geometry of spacetime, G is the gravitational constant and $T_{\mu\nu}$ is the energy and momentum tensor.

2. Milestone I - Background Cosmology

Some introduction to milestone 1

2.1. Theory

2.1.1. Fundamentals

If we assume the universe to be homogeneous and isotropic, the line elements ds is given by the FLWR-metric as follows (in polar coordinates)(Weinberg 2008, eq. 1.1.11):

$$\mathrm{d}s^2 = -\mathrm{d}t^2 + e^{2x(t)}\left[\frac{\mathrm{d}r^2}{1-kr^2} + r^2\mathrm{d}\theta^2 + r^2\sin^2\theta\mathrm{d}\phi^2\right], \tag{2}$$

where we have introduced $x(t) = \ln(a(t))$, the logarithm of the scale factor $a(t)$ include more (about k) as our first measure of time.

We further model all forms of energy in the universe as perfect fluids, only characterised by their rest frame density ρ and isotropic pressure p, and an equation of state relating the two:

$$\omega = \frac{\rho}{p}. \tag{3}$$

By conservation of energy and momentum we must satisfy $\nabla_\mu T^{\mu\nu} = 0$, which results in the following differential equations for the density include more here? of each fluid ρ_i:

$$\frac{\mathrm{d}\rho_i}{\mathrm{d}t} + 3H\rho_i(1+\omega_i) = 0, \tag{4}$$

where we have introduced the Hubble parameter $H \equiv \dot{a}/a = \mathrm{d}x/\mathrm{d}t$. The solution to eq. 4 is of the form:

$$\rho_i \propto e^{-3(1+\omega_i)x}, \tag{5}$$

where $\omega_{\mathrm{M}} = 0$ (matter), $\omega_{\mathrm{rad}} = 1/3$ (radiation), $\omega_\Lambda = -1$ (cosmological constant) and $\omega_k = -1/3$ (curvature).

With these assumptions, the solution to the Einstein equations (eq. 1) are the Friedmann equations, the first of which describes the expansion rate of the universe:

$$H^2 = \frac{8\pi G}{3}\sum_i \rho_i - kc^2 e^{-2x} \tag{6}$$

and the second describe how this expansion rate changes over time:

$$\frac{\mathrm{d}H}{\mathrm{d}t} + H^2 = -\frac{4\pi G}{3}\sum_i\left(\rho + \frac{3p}{c^2}\right). \tag{7}$$

As of now, we are primarily interested in the first Friedmann equation. By introducing the critical density, $\rho_c \equiv 2H^2/(8\pi G)$, we define the density parameters $\Omega_i = \rho_i/\rho_c$. We further define the density of the curvature $\rho_k \equiv -3kc^2e^{-2x}/(8\pi G)$, which enables us to write eq. 6 as simply:

$$1 = \sum_i \Omega_i, \tag{8}$$

where the curvature density Ω_k is included in the sum. From Eq. (5) we know the evolution of the densities in time, and if we assume the density values today, Ω_{i0}, are known (or are free parameters), then eq. 6 may also be written as:

$$H = H_0\sqrt{\sum_i \Omega_{i0}e^{-3(1+\omega_i)x}}, \tag{9}$$

which is the Hubble equation we will use further. FIXME: references - use cref

2.1.2. Measure of time and space

The main measure of time is usually the scale factor a, or its logarithm x. We then have the *cosmic time* t defined as:

$$t = \int_0^a \frac{\mathrm{d}a}{aH} = \int_0^{e^x}\frac{\mathrm{d}x}{H}. \tag{10}$$

Another temporal measure is the *conformal time* η defined as $\mathrm{d}t = e^x\mathrm{d}\eta$ yielding:

$$\eta = \int_0^{e^x}\frac{\mathrm{d}x}{e^xH} \equiv \int_0^{e^x}\frac{\mathrm{d}x}{\mathcal{H}}, \tag{11}$$

where $\mathcal{H} = e^xH$ is defined as the *conformal Hubble parameter*. ηc yields the distance to the *particle horizon*. We may also choose to measure time in terms of the *redshift* z, where $1+z = 1/a = e^{-x}$.

The comoving distance is defined as follows:

$$\chi = someintegral = \eta_0 - \eta \tag{12}$$

FIXME: check signs

TODO: double check the integral limits

The radial distance is given in terms of the comoving distance and the curvature density today Ω_{k0} as:

$$r = \begin{cases} \chi \cdot \frac{\sin\left(\sqrt{|\Omega_{k0}|}H_0\chi/c\right)}{\sqrt{|\Omega_{k0}|}H_0\chi/c} & \Omega_{k0} < 0 \\ \chi & \Omega_{k0} = 0 \\ \chi \cdot \frac{\sinh\left(\sqrt{|\Omega_{k0}|}H_0\chi/c\right)}{\sqrt{|\Omega_{k0}|}H_0\chi/c} & \Omega_{k0} > 0 \end{cases} \tag{13}$$

It is then straigtforward to define the angular diameter distance:

$$d_A = e^x r, \tag{14}$$

and the luminosity distance:

$$d_L = e^{-x} r. \tag{15}$$

TODO: derive the above?

We also have the following useful relations:

$$\frac{\mathrm{d}\eta}{\mathrm{d}x} = \frac{c}{\mathcal{H}}, \quad \frac{\mathrm{d}t}{\mathrm{d}x} = \frac{1}{H}. \tag{16}$$

TODO: explain further above

2.1.3. ΛCDM-model

In the ΛCDM model, the universe consists of matter in terms of baryonic matter (b) and cold dark matter (CDM), radiation in terms of photons (γ) and neutrinos (ν) and dark energy in terms of a cosmological constant (Λ).

$$\chi^2(h, \Omega_{m0}, \Omega_{k0}) = \sum_{i=1}^{N} \frac{(d_L(z, \Omega_{m0}, \Omega_{k0}) - d_L^{\mathrm{obs}}(z_i))^2}{\sigma_i^2} \tag{17}$$

2.2. Methods

2.2.1. Initial equation

$$\begin{aligned} \Omega_k(a) &= \Omega_{k0} e^{-2x} \left(\frac{H_0^2}{H(x)^2}\right) \\ \Omega_{\mathrm{CDM}}(a) &= \Omega_{\mathrm{CDM0}} e^{-3x} \left(\frac{H_0^2}{H(x)^2}\right) \\ \Omega_{b0}(a) &= \Omega_{b0} e^{-3x} \left(\frac{H_0^2}{H(a)^2}\right) \\ \Omega_{\gamma 0}(a) &= \Omega_{\gamma 0} e^{-4x} \left(\frac{H_0^2}{H(x)^2}\right) \\ \Omega_{\nu 0}(a) &= \Omega_{\nu 0} e^{-4x} \left(\frac{H_0^2}{H(x)^2}\right) \\ \Omega_{\Lambda 0} &= \Omega_{\Lambda 0} \left(\frac{H_0^2}{H(x)^2}\right) \end{aligned} \tag{18}$$

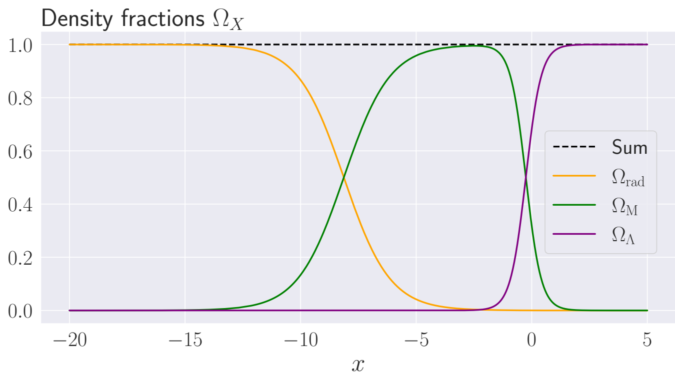

Fig. 2. Omega tests

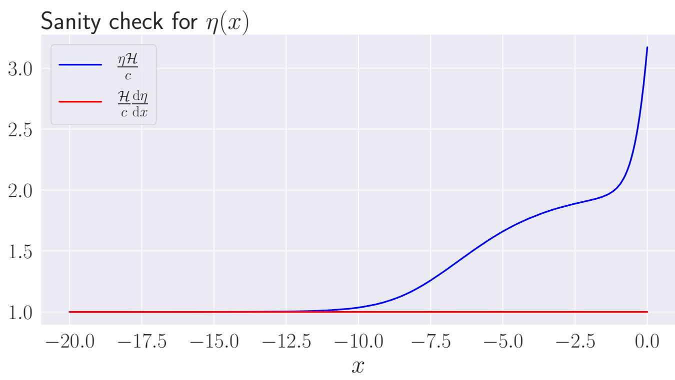

Fig. 3. Eta tests

$$\begin{aligned} \Omega_{\gamma 0} &= \frac{16\pi^3 G}{90} \cdot \frac{(k_b T_{\mathrm{CMB0}})^4}{\hbar^3 c^5 H_0^2} \\ \Omega_{\nu 0} &= N_{\mathrm{eff}} \cdot \frac{7}{8} \cdot \left(\frac{4}{3}\right)^{4/3} \cdot \Omega_{\gamma 0} \end{aligned} \tag{19}$$

2.2.2. ODEs

We solve the differential equation for $\eta(x)$, eq. **??** using an ordinary differential equation solver, with Runge-Kutta 4 RK4?as the advancement method. The initial condition is given by $\eta(x_{\mathrm{start}}) = c/\mathcal{H}(x_{\mathrm{start}})$
